

Temporal Distance Calculations for Gait

These spatiotemporal metrics are part of the common cohort of [Gait Parameters](#)].

Visual3D calculates a set of for temporal and distance information based on a set of 4 gait events (Right and Left Heel Strike and Toe Off).

- If the Events do not exist, the metrics will return values of zero.
- If a Right and Left foot segment do not exist, stride length and stride width cannot be computed.

Note that the treadmill unit vector refers to the Anterior Direction of walking.

Files for computing temporal distance

☐ Calculate For Each File

☐ Calculate For All Cmo Globals

☐ Create All Instances

- The default command will create average temporal distance values for the ACTIVE files and results can be found in the GLOBAL workspace

- **Calculate For Each File:** Calculate average values across entire trial

- **Create All Instances:** value for each sequence (multiple values per trial)

NOTE: To use the Calculate For Each File option, Calculate for Each Trial must be selected as well.

Right Foot Location	KINETIC_KINEMATIC::RFT::ProxEndPos
Left Foot Location	KINETIC_KINEMATIC::LFT::ProxEndPos
Height	METRIC::PROCESSED::HEIGHT

- If the user would like to define temporal distance metrics using a signal other than the default signal (such as the proximal end of the foot), the user can select a different signal (such as the heel target).

- The height is used to calculate [statures/second](#)

Explanation of the Metrics computed

The temporal distance calculations use snippets of the gait cycle to compute averages for each part. If a range is missing, that part will not be calculated.

Stance Time

The stance time for a given side of the body is the portion of the gait cycle when that side's leg is in contact with the ground. It is calculated as the time from that foot's heel strike event to its toe off event.

Right Stance Time = RHS-RTO

Left Stance Time= LHS-LTO

Swing Time

The swing time for a given side of the body is the portion of the gait cycle when that side's leg is not contacting the ground. It is calculated as the time from that foot's toe off event to its heel strike

event.

Right Swing Time= RTO-RHS

Left Swing Time= LTO-LHS

Step Time

The step time for a given side of the body is the portion of the gait cycle between the opposite side's heel strike event and the given side's heel strike event.

Right Step Time= LHS-RHS

Left Step Time= RHS-LHS

Double Limb Support Time

The double limb support time for a gait cycle is the total time where both feet are in contact with the ground. This is the sum of an initial double limb support phase and a terminal double limb support phase.

Right Initial Double Limb= RHS to LTO

Right Terminal Double Limb= LHS to RTO

The global mean double limb support time (stored in the global workspace as METRIC::TEMPORAL_DISTANCE::Double_Limb_Support_Time_Ave) is calculated via a two-step process. First, the mean Right_Initial_Double_Limb_Support_Time and the mean Right_Terminal_Double_Limb_Support_Time are calculated. Second, these two times are then summed to represent the average time spent during the double limb support phases throughout an entire gait cycle. This calculation captures that during a gait cycle there are two phases during which the individual is supported by both limbs: from RHS to LTO and from LHS to RTO.

Note:

Left Initial Double Limb Support (stance) = Right Terminal Double Limb Support (stance)

Left Terminal Double Limb Support (stance) = Right Initial Double Limb Support (stance)

Cycle Time

Cycle time is computed as an actual and computed. Actual uses the actual stride length / stride time. Computed speed uses the average of all the parts of the gait cycle which are seen, and sums up the parts. This is more accurate since more parts are used in the computation, and can provide a measure even if a full stride is not present in the data (RHS-RHS or LHS-LHS).

Flight Time

Flight time is the average time from LTO to RHS (ensuring no LHS or RTO events occur between LTO and RHS) and RTO to LHS (ensuring no RHS or LTO events occur between RTO and LHS).

Left flight time is calculated from LTO to RHS.

Right flight time is calculated from RTO to LHS.

Stride Length

Stride length is the distance between proximal end position of the foot at ipsilateral heel strike to the proximal end position of the foot at the next ipsilateral heel strike. Stride length and width requires a walking direction to be computed, so at least 1 completed stride needs to be present.

Right Stride Length

Right Stride length is defined as the length of the Right Stride vector from the Proximal End of the Right Foot Segment at successive RHS events

Right Stride Length Count is the number of Right Strides.

Left Stride Length

Left Stride length is defined as the length of the Left Stride vector from the Proximal End of the Left Foot Segment at successive LHS events.

Left Stride Length Count is the number of Right Strides.

Stride Length Count

Stride Length Count is the sum of Right Stride length Count and Left Stride Length Count.

Treadmill

If the person is walking on a treadmill, the distance travelled by the belt is added to the measured distance.

Stride Width

Stride width is the medio-lateral distance between proximal end position of the foot at ipsilateral heel strike to the proximal end position of the foot at the next contralateral heel strike. Calculated by taking a stride vector, and the step in between, and computing the cross product (distance between

the stride vector and the opposing step (heel) position

Left Stride Width is the perpendicular distance from the proximal end of the Left foot segment to the Right Stride vector.

Right Stride Width is the perpendicular distance from the proximal end of the Right foot segment to the Left Stride vector.

We don't actually report (or store) a left and right stride width, but rather an average stride width.

Step Length

Step length is the distance between proximal end position of the contralateral foot at the previous contralateral heel strike to the proximal end position of the ipsilateral foot at the ipsilateral heel strike. This is calculated as the distance in the walking path direction.

If the person is walking on a treadmill, the distance traveled by the belt under the stance foot is added to the measured distance.

Speed

Speed is computed using the actual stride length / actual stride time. If there are no completed strides, no speed can be computed since the stride distance can't be computed using parts.

Statures/Second

Average speed divided by the subject height

Cadence

Cadence is the rate at which a person walks, expressed in steps per minute.

In other words:

Left Steps Per Minute = 60 / [Left Step Time](#)

Right Steps Per Minute = 60 / [Right Step Time](#)

Changing the text in the temporal distance chart

In the folder in which you have placed Visual3D.exe, you should find a folder labeled [config](#). Inside this folder you will find a file labeled **custom_text.ini**

The contents of this ini file containing a mapping from the text used internally in Visual3D to the text that appears in the report graph.

The text appearing to the right of the “=” sign appears in the report.

The default config file looks like this.

Subject computation using subject name/prefix parameters

Visual3D is in the process of supporting multiple subjects within the same workspace, and across CMO/Z library workspaces. Older versions of Visual3D will not support the subject prefix extensions of this command.

When using a version of Visual3D prior to implementing multisubject support, Visual3D treats each CMO/Z file as a single subject. In this way, the temporal and distance metrics are computed in the

CMO/Z GLOBAL for the subject processed within that CMO. In the same manner, when computing the temporal and distance metrics across a library of subjects, each CMO/Z is treated as a single subject and then the subject averages are computed across CMO/Z files and placed into the workspace GLOBAL for the overall mean values across subjects.

Visual3D with multisubject support extends these metric calculations to be computed for each subject that is identified in the .C3D parameters SUBJECT section. In this way, the a single CMO/Z GLOBAL will contain the computed metrics for each subject within the CMO/Z file, prefixed with the subject's prefix identifier contained in the .C3D parameters. The GLOBAL of the CMO/Z will also contain an unprefixed set of metrics for the average across the subjects contained inside the CMO/Z file.

When working across CMO/Z files in the CMO/Z library, multisubject support for this command will treat each subject mean in each CMO/Z file as separate subject averages to be included for calculating the temporal and distance metric averages across all the subjects in the CMO/Z library.
